ABSTRACT

The avocado seeds were collected from Dilla and Wonago in gedeo zone, southern part of Ethiopia for oil extraction and biodiesel production. The collected seeds were oven dried and crushed in to powder by mortar and pestle. A soxhlet extraction was used for extraction of the oil. The solvent used for oil extraction was n-hexane. The extracted oil was separated from the solvents by vacuum rata evaporator. The oil content, biodiesel content and the physico-chemical parameters of the oil as well as the biodiesel were determined .The oil content and biodiesel content is 27.6% and 95.2% for avocado seed grown in wonago and 27.2% and 94.86% for avocado seed grown in Dilla respectively. The physico-chemical parameters of the oil and biodiesel were determined and the result shows that the acid value of (4, 4.3, 0.89, 0.92), saponification value (223, 219), Kinematic viscosity (36, 7, 5.02, 37.44, 5.15), Density (933, 882, 936, 884 g/ml), Higher heating (38, 40.5, 37, 40), Ester content (95.2, 94.86) respectively. Based on the GC-MS analysis of the biodiesel, four FAME compounds were identified. These are methyl palmitate, methyl linoleate, methyl olate and methyl stearate. From the physicochemical properties of the biodiesel determined avocado seed oil methyl ester could be used as an alternative energy resource in diesel engine.

1. INTRODUCTION

Increasing energy demands, depletion of fossil fuels and environmental pollution make the world under crises now a day’s. This is because of many countries worldwide are still heavily dependent on petroleum as their main source of electricity and transportation fuel. The only possible solution to solve this crisis is to find a sustainable (renewable), economically feasible and environmentally friendly source of alternative energy is necessary. There are many alternative energy sources such as hydropower, wind, solar, geothermal and biomass. Biodiesel fuel is a renewable energy resource which is made from vegetable oils available around us [1-3].

Avocado seed (Persea americana) is a waste where so many people are throwing away after using the fruit flesh. It is one of the most popular fruit in geedo zones as a result there is a significant rise in avocado fruit consumption and consequently an increase in the Avocado seed waste generation. Therefore, alternative routes are needed for this waste management.

This waste can be used for various applications. The presence of nitrogen allows it to be directly used as fertilizer or as soil improver (or compost) [4]. On the other hand, waste Avocado seed have oil content in the order of 12-30 wt% which can be recovered and used for biodiesel production.

Biodiesel is a clean, renewable, biodegradable, environmentally benign, energy efficient and diesel substituent fuel used in diesel engine. It is a carbon neutral fuel because there is no overall increase in CO$_2$ in the atmosphere due to recycling by the growing plants used to feed the biodiesel industry [4].

Emissions of SO$_2$, SO$_3$, CO, unburnt hydrocarbons and particulate matter are lower than that of petroleum diesel [5,6]. The most common process used to produce biodiesel is through transesterification, a reaction between triglycerides and an alcohol with a low molecular weight (ethanol or methanol) in the presence of a basic catalyst (NaOH or KOH), to obtain esters and glycerol [7-9]. Transesterification is a three-step reversible reaction of vegetable oils or animal fats with a methanol to form fatty acid methyl esters (FAMEs) and glycerol as a final product [10-11].

![Figure 1. Base catalyzed transesterification processes.](image)

The reaction mechanism for the formation of fatty acid methyl esters (FAME) is described as follows (Figure 2).
Figure 2. Reaction Mechanism for base catalyzed transesterification.
Currently, about 84% of the world biodiesel production is met by rapeseed oil. The remaining portion is from sunflower oil (13%), palm oil (1%), soybean and others (2%). Since more than 98% of the biodiesel is made from edible oil, there are many claims due to the depletion of edible oil supply worldwide. Therefore in order to overcome these devastating phenomena, the feedstock for the biodiesel production must be replaced by non-edible oil, frying oil and oil extracted from waste substances. Therefore, for this study oil extracted from the waste Avocado seeds grown in Wonago and Dilla were used for the production of biodiesel because this have two advantages such as waste management and the oil is non-edible as a result it does not compete with food security.

### 1.2. Objectives of the study

#### 1.2.1. General objective

The general objective of this study is to Determine the oil and biodiesel content, physicochemical properties of the oil extracted and biodiesel from avocado seed (Persea Americana) grown in Wonago and Dilla (Gedeo zone), southern Ethiopia.

#### 1.2.2. Specific objectives

The specific objectives were:

- Extraction of crude oil from Avocado seed by Soxhlet apparatus and maceration using n-hexane and ethyl acetate as an extracting solvent.
- Determine the amount of oil from the waste Avocado seed grown in different environments.
- Determine the optimum conditions/parameters (such as reaction temperature, alcohol-to-oil molar ratio, type and concentration of catalyst and reaction time) for the yield and quality of the biodiesel produced.
- Determine the physicochemical properties of crude oil extract, oil blends, biodiesel and biodiesel blends such as acid value, density, kinematic viscosity, iodine value and higher heating values.
- Compare the physicochemical properties of oil, oil blends, biodiesel and biodiesel blends with the biodiesel standards (ASTM D6751 and EN14214 standards).
- Analyze the chemical composition of the biodiesel using chromatographic and spectroscopic techniques such as gas chromatography coupled with mass spectrometry (GC-MS) and FT-IR spectrometry.

### 2. MATERIALS AND METHODS

#### 2.1. Materials

#### 2.1.1. Chemicals and reagents

Methanol (99%), sodium hydroxide, sulfuric acid (98%), n-hexane, ethyl acetate, sodium thiosulfate, phenolphthalein, ethanol (96%), anhydrous sodium sulphate, avocado seed oil and potassium hydroxide.
2. 1. 2. Instrumentations

Soxhlet apparatus, Rotary evaporator, GC-MS, FT-IR, bomb calorimeter, viscometer, hot plate, thermometer, round bottom flask, separatory funnel, mortar and pestle were used.

2. 2. Experimental

The biodiesel produced from avocado seed oil and methanol with sodium hydroxide as catalyst was studied in laboratory experiments.

2. 2. Waste Avocado seed sample preparation

Fresh Avocado seeds were collected from wonago and Dilla. After that the waste Avocado seeds were prepared and oil was extracted for biodiesel production.

2. 3. Extraction Methods

2. 3. 1. Extraction of oil from waste Avocado seed by Soxhlet apparatus

Oven dry of waste Avocado seeds were grounded in to powder by using pestle and mortar. After that 100g of the sample were loaded in to thimble in Soxhlet apparatus. Next to that extraction was carried out using 500 ml normal hexane at 68 ºC (boiling temperature of hexane) for 48 h in an electrical heater. The mixture of the extracted oil and the hexane was separated by rotary evaporator and the percentage of the oil was calculated by the following formula: 

% Oil = Mass of Oil x 100 / sample

2. 4. Analytical methods

2. 4. 1. Analysis of biodiesel by GC-MS

The composition of the raw material was determined by gas chromatography equipment equipped with a flame ionization detector and with a DB 23 column. Firstly, the methyl ester was obtained using 1%wt of sodium hydroxide and methanol. The reaction was carried out at 45 ºC, 55 ºC and 65 ºC with a reaction time of 60 minutes. After the reaction, the excess methanol was evaporated under a vacuum using a rota-evaporator. Then, the mixtures of ester and glycerol were separated by separator funnel, and the methyl ester portion was purified by washing with water to remove the excess catalyst and the glycerol. After that, the esters were dried with anhydrous sodium sulfate.

Next 0.1 ml of biodiesel was diluted to 10 ml using n-heptane (HPLC-grade, Merck). The sample was analyzed in a HP gas chromatograph model STAR 3600CX (Lexington, MA) equipped with a mass spectrometry and with a HP5 column (30 m x 0.320 mm, J&W Scientific, Folsom, CA).Injector and detector temperatures were set at 250 ºC and 300 ºC, respectively.

The carrier gas used is helium at 46 ml/min. Air and hydrogen flow rates are 334 and 34 ml/min, respectively. The program of the oven temperature is as follows: starting at 50 ºC for 2 min; from 50 ºC to 180 ºC at 10 ºC/min; 180 ºC is held for 5 min; from 180 ºC to 240 ºC at 5 ºC/min. Identification of different fatty acid methyl esters (FAMEs) was done based on a reference standard.
2. 4. 2. FT-IR spectrometry

The FT-IR spectra were recorded using KBr pellets. The samples were prepared as follows: 2 mg of the studied samples was grounded together with 200 mg KBr into the fine powder with the particles size below 5mm and compressed to form of clear disk. The FT-IR spectra will be recorded using Brücker Tensor-27 spectrometer at ambient temperature in the wave number 4000-400 cm$^{-1}$.

2. 5. Experimental design

2. 5. 1. Experimental Treatments

A basic catalysts (NaOH) was used at different reaction temperatures to study at which catalyst amount and temperature an optimum biodiesel is produced from the oils of waste Avocado seed. In addition to this blending of the biodiesel was conducted with petroleum diesel. Finally the physicochemical properties of the oil extracted from waste Avocado seed, biodiesel and blended biodiesel was determined.

2. 6. Determination of the physicochemical properties

Density, specific gravity, kinematic viscosity, acid value, saponification value, iodine value, peroxide value, ester content and higher heating value oil of avocado seed, biodiesel and blended biodiesel was determined.

3. RESULTS AND DISCUSSION

3. 1. GC-MS and FT-IR analysis of biodiesel prepared from waste avocado seed

Based on GC-MS analysis, the FAME of biodiesel prepared from waste avocado seed oils of Wonago and Dilla four compounds were identified as described in detail in Table 2 below.

3.2. Physicochemical properties

The biodiesel and biodiesel blends had lower specific gravity, density and kinematic viscosity compared to Avocado seed oil (Table 3). This is due to the fact that Avocado seed oil contains three esters combined together while the biodiesel contains a single ester. Conversely biodiesel and biodiesel blends had higher heating value than the Avocado seed oil. The main reason for the increased higher heating value is due their lower specific gravity and kinematic viscosity. Besides to this the higher heating values of the biodiesel blends were larger than the biodiesel but lower than the petroleum diesel.

This is due further reduction in specific gravity and kinematic viscosity of the blends. The carbon residue of the avocado seed oil was higher than the biodiesel, biodiesel blends and petroleum diesel. This is due to the fact that there will be no complete combustion as a result of the higher kinematic viscosity of the oil.

Even though the kinematic viscosity of petroleum diesel was lower than the biodiesel and biodiesel blends its carbon residue was higher. This is because of the incomplete combustion of the non-oxygenated hydrocarbons and aromatic compounds in petroleum diesel. The higher heating value and carbon residue were increasing as the amount of the petroleum diesel increases in the blend.

The main reason for the increasing of the higher heating value is the decrease of specific gravity and kinematic viscosity of the blends. The higher heating values of biodiesel blends lie between the heating values of their constituents. Generally the physicochemical properties of the biodiesel and biodiesel blends (up to C<sub>20</sub>) lie within the biodiesel standard limits. Therefore these biodiesel and biodiesel blends can be used in diesel engine to substitute petroleum diesel (Table 3).

3.4. FTIR spectra of avocado oil, biodiesel and petroleum

The oil, biodiesel prepared from avocado seed oil and petroleum diesel was analyzed by FT-IR. The major change that takes place during the conversion from triglyceride oil to biodiesel was the gain of a CH₃ carbon in the methyl ester (biodiesel) product, which is found
in the range of 1438-1459 cm\(^{-1}\) which is not present in the spectra of the oil. All other functional groups are the same for both the oil and biodiesel molecules. Biodiesel results in the formation of carbon hydrogen bonds at 2855-3008 cm\(^{-1}\), ester functionality at 1738-1759 cm\(^{-1}\), CH\(_3\) terminal carbons at 1438-1459 cm\(^{-1}\), and carbon oxygen bonds at 1171-1197 cm\(^{-1}\). In addition to this, there was a CH\(_3\) carbon stretch at 1459 cm\(^{-1}\) which indicates that the product methyl ester did form during the reaction.

There is a sharp Carbonyl stretching at 1742 cm\(^{-1}\), which is characteristic of the ester in the product but not in the petroleum diesel it does not oxygen in its molecule as a result it does not contain carbonyl functional group. A peak at 1197 cm\(^{-1}\) is carbon oxygen stretch and compliments the carbonyl peak in characterizing the product as an ester. Other identifying peaks found in the product were at 2926 cm\(^{-1}\) and 2855 cm\(^{-1}\) that represents sp\(^3\) hybridized carbon molecules that are found in the long carbon chain of the biodiesel.

The presence of fewer peaks in the fingerprint region of the biodiesel spectra in comparison to that of the triglyceride further confirms formation of the fuel product. This is as a result of the biodiesel being mono alkylated, unlike the more complex tri-alkylated triglyceride oil. Long saturated carbon chain allows for more carbon bonds to be broken; thus, producing more energy.
Figure 3. FTIR spectra of oil, biodiesel and petroleum diesel
3.5. Analysis of mass fragmentation of Fatty Acid Methyl Esters coffee biodiesel

Gas chromatography - coupled with mass spectroscopy was used to analyze the chemical composition of the biodiesel prepared from waste avocado seed oil of a wonago and Dilla. As their mass spectra is shown in Figures 2a to 2d, methyl palmitate, methyl linoleate, methyl oleate and methyl stearate were identified as major components at a retention times of 7.34, 9.28, 9.83 and 10.5 minutes respectively in all of the two avocado grown in different areas. The molecular ion (parent) peaks of methyl palmitate, methyl linoleate, methyl oleate and methyl stearate were observed at 270, 294, 296 and 298 respectively as expected. It is interesting to observe that the saturated FAMEs detected in the biodiesel from waste avocado (methyl palmitate and methyl stearate) show CH$_3$OC(=OH$^+$)CH$_2$ fragment and appears at m/z = 74 as the base peak (100%) which is the result of McLafferty rearrangement during the MS analysis due to a six member ring structure of an intermediate. Methyl linoleate shows [CH$_2$=CHCH=CHCH$_2$]$^+$ fragment which appears at m/z = 67 as the base peak (100%). Methyl oleate shows [CH$_2$=CHCH$_2$CH$_2$]$^+$ fragment which appears at m/z = 55 as the base peak (100%).

The methyl palmitate base peak ion at m/z = 74 undergoes McLafferty rearrangement loosing the methyl ester which is fragmented between the α and β substituted carbons while the ion at m/z = 87 is fragment between C$_4$ – C$_5$ also loosing methyl ester and a hydrogen atom. An ion with m/z = 57 is fragmented between C$_3$ and C$_4$ losing a methylene diole and three hydrogen atoms via McLafferty rearrangement. Methyl linoleate’s molecular ion occurs at 294 m/z. Both ions at m/z = 67 and 81 represent hydrocarbon fragments with general formula [C$_n$H$_{2n-3}$] loosing dialkenes and a hydrogen atom. Methyl oleate’s parent peak is observed at m/z = 296.
Figure 4. Mass spectra of methyl palmitate, methyl linoleate, methyl oleate and methyl stearate.

The peak at m/z = 74 represents the rearranged McLafferty methyl ester fragment while the peak at m/z = 87 represents fragmented hydrocarbon ions with general formula \( [\text{CH}_3\text{OCO(CH}_2)_n] \). Methyl stearate’s molecular ion occurs at m/z = 298. The ion present at m/z = 74 corresponds to the McLafferty rearranged methyl ester fragmented between the \( \alpha \) and \( \beta \) carbons while the ion at m/z = 87 represents loss of methyl ester and a hydrogen atom fragmented between C\(_3\)-C\(_4\) respectively. Molecular ion at m/z = 67 and 81 represent hydrocarbon fragments with general formula \( [\text{C}_n\text{H}_{2n-3}] \) due to loss of alkenes and a hydrogen atom.

4. CONCLUSION

Biodiesel from avocado seed oil is obtained by transesterification process using sodium hydroxide as catalyst. Optimum amount of methyl ester content from avocado seed oil is obtained at 65 °C with methanol to oil molar ratio 6:1. From the physicochemical properties of the biodiesel determined avocado seed oil methyl ester could be used as an alternative energy resource in diesel engine.
